

LABORATORY 2 – GIT COMMANDS

EXPLANATION

1. `git init` - This one is like setting up a new project folder for Git. You use it when you're starting a new project and want Git to keep track of your work. It creates a hidden `.git` folder where Git stores everything it needs to track your project's changes.
2. `git add` - This command is like saying, "Hey Git, pay attention to this file! I want to keep track of this change." When you've made changes to files and want to include them in your next "snapshot" (commit), you first need to stage them with `git add`.
3. `git commit` - After you've staged your changes with `git add`, `git commit` is how you save them permanently in Git. It's like taking a snapshot of your code at that moment. Each commit gets a message so you (and others) can remember what changes were made.
4. `git branch` - Think of branches like parallel universes in your project. They let you work on different features or fixes without messing up the main project. `git branch` is how you create and manage these different versions.
5. `git remote` - This one's all about connecting your local project to a remote server (like GitHub or GitLab). It tells Git where to send your changes when you push them or where to pull new changes from.
6. `git push` - Once your changes are committed locally, you use `git push` to send them up to a remote server (like GitHub). It's like uploading your work so everyone else can see it, or so you can back it up.
